Introduction

Lamiaceae Martinov is one of the largest plant families represented by about 258 genera and 3500 species in the world (Duarte & Lopes 2007). According to Davis (1982), Lamiaceae family has 45 genera and about 546 species distributed in Turkey. Turkey is a gene center of this family to which genus Lamium L. belongs (Başer 1993).

The most important characteristic of the Lamiaceae are glandular trichomes distributed on vegetative and reproductive organs (Werker 2006). These trichomes produce essential oils and their structure has been studied for systematic purpose (Hanlidou et al. 1991; Vrachnakıs 2003). The commercial value of these essential oils is recorded in lots of special studies, as well as in relation with the morphology, structure and secretion of trichomes (Amelunxen et al. 1969; Heinrich et al. 1983; Dudai et al. 1988; Antunes & Sevinate-Pinto 1991).

Abstract

The types of glandular trichomes and their distribution on the vegetative and reproductive organs of Lamium orientale (syn. Wiedemannia orientalis) are studied for systematic purposes in this paper. Two morphologically different types of glandular trichomes (peltate and capitate) are described. Peltate trichomes are characterized by a short stalk, which is connected with a large spherical head composed of four cells in a single layer. Capitate glandular trichomes are subdivided into capitate type A and capitate type B. On the vegetative organs peltate trichomes are abundant, while on reproductive organs capitate trichomes are numerous and the peltate trichomes are rare or absent.

Keywords: Lamium orientale, Lamiaceae, trichomes
This paper provides first comparative investigation on glandular trichomes of *L. orientale* (Fisch. et C.A. Mey.) E.H.L. Krause formerly known as *Wiedemannia orientalis* Fisch. et C.A. Mey. (Mill 1982) and nested in *Lamium* genus on the base of recent phylogenetic studies (Bendiksby *et al.* 2011; Atasagun *et al.* 2015). It is aimed to evaluate the usefulness of characters of glandular trichomes for systematic purpose.

**Material and methods**

Plant material of *L. orientale* was collected in Amasya (on roadside between Yediküllü Bird Paradise protected area and Ortaova village, 500 m, April 2008, İ. Öztürk Çalı 376), which is a city in the Black Sea region of Turkey. The specimens were kept as a herbarium material deposited at Gazi University Herbarium (GAZI). Flora of Turkey (Davis 1982) was used for taxonomical description.

The plant material was fixed in 70% alcohol for trichome evaluation properties. Glandular trichomes were obtained from transverse and surface sections of vegetative (stem, leaf blade, petiole) and reproductive organs (calyx, corolla) of *L. orientale*. Gandular trichomes preparations were made by hand using commercial razor blades under a Leica ICC50 HD binocular light microscope. Sartur reagent was applied to the sections for investigation of anatomical tissues (Çelebioğlu & Baytop 1949). The types of glandular trichomes and their distribution were described and classified according to Metcalfe & Chalk (1972), Payne (1978) and Navarro & El Oualidi (2000).

**Results and discussion**

The great diversity of plant trichomes has interested botanists by their adaptive and taxonomic values. The morphology and distribution of glandular trichomes are often applied as taxonomic characters at subfamiliar level in Lamiaceae family (El-Gazzar & Watson 1970; Abu-Asab & Cantino 1987; Cantino 1990). There are two different types of glandular trichomes on vegetative and reproductive organs of *L. orientale* – peltate and capitate (Tab. 1).

Peltate glandular trichomes of *L. orientale* have a basal epidermal cell, a very short monocellular stalk and a broad round multicellular secretory head consisting of four cells in the single shield (Tab. 1; Fig. 1 A, B). The anticinal wall of the stalk cell is cutinized.

Secretory materials of such trichomes together with an outer layer of the cell walls are secreted from the head into a space formed in result of elevation of their common cuticle (Özdemir & Altan 2005). Peltate trichomes of other Lamiaceae representatives usually have multicellular secretory head consisting of up to 16 cells, a monocellular stalk and a basal epidermal cell (Corsi & Bottega 1999; Hallahan 2000; Kamatou et al. 2006, 2007). In this study it was also found that peltate trichomes are more abundant on the vegetative organs and rare on the reproductive organs of L. orientale (Tab. 2), what confirms some previous findings for other species (Serrato-Valenti et al. 1997; Corsi & Bottega 1999).

Capitate glandular trichomes are the most common in Lamiaceae family, but they are more variable in stalk length and head shape. Presence of such trichomes is a significant taxonomic character playing also important role for pollination (Navarro & El Oualidi 2000). Such trichomes are composed of a basal epidermal cell, unicellular to multicellular stalk and a large unicellular, bicellular or multicellular secretory head. Capitate trichomes are subdivided into two types – capitate type A and capitate type B (Tab. 1). Capitate type A trichomes have unicellular, bicellular or multicellular head and stalk of one to two cells (Fig. 1 C, D). A high percentage of these trichomes have one roundish head cell. Capitate type B trichomes have an oblong unicellular head and a short unicellular stalk. However, sometimes occur capitate glandular trichromes of type B with bicellular stalk (Fig. 1 E, F). This type of capitate trichomes was only observed on calyx and corolla (Tab. 2).

Presence of glandular trichomes, especially on the flowers of L. orientale is noteworthy. Such trichomes on reproductive organs of some Lamiaceae (e.g., Salvia L.) have also been reported by Werker et al. (1985a, 1985b), but only a small number of Lamiaceae species has been already studied.

Conclusions

Features of glandular trichomes are useful tool for distinguishing species in Lamium genus. Presence of capitate type A, capitate type B, and peltate glandular trichomes on reproductive organs of L. orientale can be used for further taxonomic investigations in Lamium.
